1.  $v_d = i/(nqA)$  ... Charge drift velocity in a current  $i$  in a conductor with number density  $n$  and area  $A$ .
2.  $P = IV$  ... Relationship between power, current, and voltage.
3.  $\vec{F} = q\vec{v} \times \vec{B}$  ... The Lorentz force on a charge  $q$  with velocity  $\vec{v}$  in a magnetic field  $\vec{B}$ .
4.  $\vec{F} = I\vec{L} \times \vec{B}$  ... The Lorentz force on a conductor of length  $\vec{L}$  carrying a current  $I$  in a magnetic field  $\vec{B}$ .
5.  $\int \vec{B} \cdot d\vec{l} = \mu_0 I_{enc}$  ... Ampère's Law.
6.  $\epsilon = -Nd\phi/dt$  ... Faraday's Law.
7.  $\phi = \vec{B} \cdot \vec{A}$  ... Definition of magnetic flux.
8. Faraday's Law using **Inductance**, M:  $\mathcal{E} = -M \frac{dI}{dt}$ .
9. Typically, we refer to *mutual inductance* between two objects as  $M$ , and *self inductance* as  $L$ . Self-inductance:  $\Delta V = -L(dI/dt)$ .
10. Units of inductance:  $V \cdot s \cdot A^{-1}$ , which is called a Henry, or H.
11.  $B = \mu_0 nI$  ... The B-field of a solenoid,  $n = N/L$  is the turn density, and  $I$  is the current.

Figure 1: (Left) A current  $I$  experiences a force  $F$  in a  $B$ -field.

## 2 Chapter 11: Magnetic Forces and Fields

- Consider Fig. 1 (left). In each of the three cases, determine the direction of the  $B$ -field given that  $F$  is the Lorentz force.

- a: towards page
- b: left
- c: out of page

- Consider Fig. 1 (right). **The Hall Effect.** An  $E$ -field exists in the vertical direction and a  $B$ -field is perpendicular to the direction of charge velocity. (a) Show that if the  $E$ -field force on a charge balances the Lorentz force on a charge, that  $v = E/B$ . (b) If the  $E$ -field is constant,  $E = \Delta V / \Delta x$ . Show that

$$\begin{aligned} a. | F &= q\vec{v} \times \vec{B} \\ F_B &= qvB \quad F_E = qE \\ \frac{qE}{q} &= \frac{qvB}{q} \Rightarrow E = vB \end{aligned} \quad \Delta V = \frac{B \Delta x I}{n q_e A} \quad (1)$$

where  $n$  is the charge carrier density,  $q_e$  is the electron charge,  $A$  is the cross-sectional area of the conductor, and  $I$  is the current. Plug in  $B = 1.33 \text{ T}$ ,  $\Delta x = 2 \text{ cm}$ ,  $I = 10 \text{ A}$ ,  $n = 2 \times 10^{28} \text{ m}^{-3}$ ,  $A = 1 \text{ mm}^2$ , and  $q_e$  is the charge of an electron.

$$q_e = 1.6 \times 10^{-19}$$

$$1 \text{ mm}^2 = 1 \times 10^{-6} \text{ m}^2$$

$$\Delta V = \frac{B \Delta x I}{n q_e A} \Rightarrow \Delta V = \frac{(1.33)(0.02)(10)}{(2 \times 10^{28})(1.6 \times 10^{-19})(1 \times 10^{-6})} = 8.3 \times 10^{-5} \text{ V}$$

- A proton has a magnetic field due to its spin. The field is similar to that created by a circular current loop  $0.65 \times 10^{-15} \text{ m}$  in radius with a current of  $1.05 \times 10^4 \text{ A}$ . Find the maximum torque on a proton in a  $2.50\text{-T}$  field. (This is a significant torque on a small particle.)

$$A = \pi r^2 = \pi (0.65 \times 10^{-15})^2 = 1.3 \times 10^{-30}$$

$$\tau = (1.05 \times 10^4)(2.50)(1.3 \times 10^{-30}) = 3.4 \times 10^{-26} \text{ Nm}$$

## 3 Chapter 12: Sources of Magnetic Fields

- (a) What is the  $B$ -field inside a solenoid with 500 turns per meter, carrying a current of  $0.3 \text{ A}$ ? (b) Suppose we insert a piece of metal inside the solenoid, boosting  $\mu_0$  by a factor of 5000. What is the new  $B$ -field?

$$a) \quad B = \mu_0 n I \quad \mu_0 = 4\pi \times 10^{-7} \quad n = 500 \quad I = 0.3 \quad B = (4\pi \times 10^{-7})(500)(0.3) = 1.9 \times 10^{-4} \text{ T}$$

$$b) \quad B = (5000)(4\pi \times 10^{-7})(500)(0.3) = 0.94 \text{ T}$$

Figure 2: A basic diagram of a *toroid*, which is a solenoid wrapped into a circular tube.

2. Consider Fig. 2. **Mass spectrometer.** Suppose that the velocity of the charged particles moving to the right is  $v = E/B$ . (a) Show that if  $v = E/B$ ,  $F_{net} = 0$  in the region in the top left<sup>1</sup>. (b) Recall that the centripetal force on a particle of mass  $m$  is  $mv^2/r$ . Set this equal to the magnitude of the Lorentz force to prove that

a)  $F_{net} = qE - qvB = 0$   
 $qE = qvB$   
 $E = vB = 0$   
 $v = E/B = 0$   
 $r = \frac{mv^2}{qB^2}$   
 $b) qvB = \frac{mv^2}{r} \Rightarrow r = \frac{mv}{qB} = r = \frac{mE}{qB^2}$   
 $r = \frac{mE}{qB^2}$

The mass of an oxygen nucleus is 16 times that of a proton (mass of proton:  $1.67 \times 10^{-27}$  kg). Suppose oxygen ions with the charge of 1 proton are sent through the mass-sepectrometer. The E-field is 10 V/m, and the B-field is 0.01 T. What is the distance  $r$ ?  $m = 16(1.7 \times 10^{-27}) = 2.7 \times 10^{-26}$  kg

distance  $r = \frac{(2.7 \times 10^{-26})(10)}{(1.6 \times 10^{-19})(0.01)^2} = 0.017m$

#### 4 Chapter 13: Electromagnetic Induction

Figure 3: A voltage is induced on a loop by a changing B-field.

1. The magnetic field in Fig. 3 flows out of the page through a single ( $N = 1$ ) loop, and changes in magnitude according to

$$\frac{\Delta B}{\Delta t} = \frac{B_0}{T_0} (\sin(2\pi ft)) \quad (3)$$

The loop has a radius  $r$ . (a) In terms of the given variables, what is the induced voltage in the circuit? (b) If  $B_0 = 0.1$  T,  $r = 0.1$  m,  $f = 10^3$  Hz, and  $T = 1$  ms, what is the induced emf at  $t = 0$ ? (c) What about  $t_1 = 0.16$  ms? (d) What is the current through the resistor at  $t_1$ ?

a)  $\mathcal{E} = -N \frac{d\Phi}{dt}$   
 $\mathcal{E} = \frac{d(BA)}{dt} \leftarrow \pi r^2$   
 $\mathcal{E} = \frac{B_0}{T_0} (\sin 2\pi ft) \pi r^2$   
 b) It will be 0 because  $t=0$  and therefore  $\mathcal{E}=0$   
 c)  $\pi (0.1)^2 \left( \frac{0.1}{0.001} \right) (\sin(2\pi (10^3)(0.16 \times 10^{-3})) = 3.14 \times 0.08 = 0.057V$   
 d)  $V = IR \Rightarrow I = V/R = \frac{0.057V}{5\Omega} = 0.011 \text{ Amps}$

<sup>1</sup>Molecules that do not have this velocity will hit the sides of this portion of the instrument.

## 5 Chapter 14: Inductance

1. What is (a) the rate at which the current through a 0.50-H coil is changing if an emf of 0.150 V is induced across the coil?

$$\text{emf} = -M(dI/dt) = \text{emf}/-M$$

$$\text{emf} = 0.150 \text{ V}$$

$$-M = .5$$

$$0.15/-0.5 = \boxed{0.3 \text{ A/s}}$$

2. When a camera uses a flash, a fully charged capacitor discharges through an inductor. In what time must the 0.100-A current through a 2.00-mH inductor be switched on or off to induce a 500-V emf?

$$\mathcal{E} = 500 \quad L = 2.00 \text{ mH or } .002 \text{ H}$$

$$\Delta I = .1$$

$$\Delta t = \frac{L}{\mathcal{E}} \Delta I$$

$$\Delta t = (0.002)(0.1)/500 = \boxed{4 \times 10^{-7} \text{ s}}$$
