Measuring the Strength of a Magnetic Field

By: Kiara Valencia
Brianna Preciado

Background

Magnetic field: a vector that describes the magnetic influence on electric charges, electric currents, and magnetic materials

The Problem

A cosmic ray proton moving toward the Earth at $7.00 \times 10^7 \text{ m/s}$ experiences a magnetic force of $2.10 \times 10^{-16} \text{ N}$.

What is the strength of the magnetic field if there is a 45° angle between it and the proton's velocity?

From Chapter 22.4 Magnetic Field Strength: Force on a Moving Charge in a Magnetic Field

What We Know

F is the force

q is the charge

v is the velocity

B is the magnetic field strength

θ is the angle between the direction of velocity and the magnetic field strength

Step 1

Using the equation for the magnitude of force,

$$F = qvB\sin\theta$$

we are going to rewrite the equation in terms of magnetic field strength

$$B = F / qv\sin\theta$$

Step 2

We are then going to plug in our information into the equation & solve

$$F = 2.10 \times 10^{-16} \text{ N} \quad q = 1.60 \times 10^{-19} \text{ C} \quad v = 7.00 \times 10^7 \text{ m/s}$$

$$B = (2.10 \times 10^{-16} \text{ N}) / ((1.60 \times 10^{-19} \text{ C})(7.00 \times 10^7 \text{ m/s})(\sin 45^\circ))$$

This substitution gives us the answer

$$B = 2.65 \times 10^{-5} \text{ T}$$

Conclusion

We found that the strength of the magnetic field is $2.65 \times 10^{-5} \text{ T}$.

We know that the strength of the Earth's magnetic field ranges from 25 to 65 μT because of the different areas.

As a result, our answer is consistent with the known strength of the magnetic field on surface.
