

Wednesday Warm Up: Unit 4, AC Generators

Prof. Jordan C. Hanson

March 25, 2026

1 Memory Bank

- $\epsilon = -N\Delta\phi_m/\Delta t$... Faraday's Law
- $\phi_m = \vec{B} \cdot \vec{A} = BA \cos(\theta)$... Definition of magnetic flux
- $\epsilon(t) = \epsilon_0 \sin(\omega t)$... AC voltage generated by generator. ϵ_0 is proportional to ω .
- $P_{max} = V_{max}^2/R$... Max power of an AC generator.
- $P_{ave} = \frac{1}{2}P_{max}$... Average power of an AC generator.

2 AC Generators

1. Consider Fig. 1. Suppose that the angle between the area vector and the magnetic field is $\theta = \omega t$. Show that

$$\phi(t) = BA \cos(\omega t) \quad (1)$$

2. Given Eq. 1, it turns out that the voltage generated in the loop is proportional to $\sin(\omega t)$ and ω itself. That is,

$$\epsilon(t) = BA\omega \sin(\omega t) \quad (2)$$

What is the voltage at a time $t = 1/240$ seconds, $\omega = 120\pi$ Hz, $B = 0.1$ T, and $A = 0.01$ m²?

3. At what time is the voltage zero?

Figure 1: A schematic of the concept of an AC generator.

4. Suppose the AC generator in Fig. 1 has $V_0 = 12$ V/Hz, so that $\epsilon(t) = V_0\omega \sin(\omega t)$. If the AC generator pushes current through a resistance $R = 50\Omega$, what is the **average** power generated?

5. What is the average power generated if the angular frequency is doubled?
